

NSW ARBOVIRUS SURVEILLANCE & MOSQUITO MONITORING PROGRAM 2016-2017

Weekly Update

Date: 13/Jan/2017

SUMMARY

- **Climate:** over the last week, precipitation was limited to few regions and was light. For December, rainfall was average for most of the state with parts of the coast and northern inland being drier than normal, and parts of the west being wetter than average. Maximum and minimum temperatures for December were 2-3 degrees above average.
- **Three Month Forecast:** for January to March 2017, rainfall predictions for NSW are for below average precipitation, with a higher probability of eastern areas being drier than average. Maximum and minimum temperatures are predicted to be above normal and warmer in eastern areas. According to the BOM as of 3/Jan/17, the El Niño-Southern Oscillation remains neutral.
- **Tidal:** the next series of high tides that may result in larval hatching are occurring now over 10-14/Jan/2017.
- **MVEV models:** the data relevant to both the Forbes' and Nichols' hypotheses have been updated to the end of December 2016 and both theories remain inconsistent with past MVEV outbreaks.
- **Mosquito Numbers Inland:** mosquito collections were higher this week with the warmer weather. Griffith collections were 'very high' and the location yielded over 10,000 mosquitoes. Elsewhere, collections were 'medium' to 'high'.
- **Mosquito Numbers Coast:** most locations produced 'low' mosquito numbers.
- **Mosquito Numbers Sydney:** mosquito numbers were up at the sites where *Aedes vigilax* dominate notably the Georges River sites and Homebush. At other locations, collections were 'low'.
- **Arboviral Isolates:** there was one Ross River virus from Leeton this week.
- **Chicken Sentinel Seroconversions:** there have been no seroconversions.
- **Human Notifications:** there were an additional 32 Ross River virus notifications, which is a lot for one week in January (average is around 15). For the current fiscal year, the Ross River virus notifications are now only slightly below average, with December reports being more than double the average. There have been few notifications of Barmah Forest virus disease.

Comment: the hotter weather has meant that mosquito numbers were higher this week, with some very big collections from the Riverina. Fortunately there were fewer detections of virus over the last two weeks. Human notifications of Ross River virus for January are already around double the average for the month and large numbers of cases are expected to be reported in the near future.

ENVIRONMENTAL CONDITIONS

Rainfall

Rainfall across Australia for the week ending 12/Jan/2017 is depicted on the left and monthly rainfall deciles for December 2016 are on the right. Over the last week, precipitation was limited to few regions and was light. Rainfall during December (right graph below) was average for most of the state with parts of the coast and northern inland being drier than normal, and parts of the west being wetter than average. Maximum and minimum temperatures for December were 2-3 degrees above average.

Three Month Rainfall & Temperature Forecast

For January to March 2017, rainfall predictions for NSW are for below average precipitation, with a higher probability of eastern areas being drier than average. Maximum and minimum temperatures are expected to be above normal across the state and warmer in eastern areas. The following pages contain graphics of the seasonal outlook:

www.bom.gov.au/climate/outlooks/#/rainfall/median (Rainfall outlook).

www.bom.gov.au/climate/outlooks/#/temperature/summary (Max & min temperature outlook).

According to the BOM as of 3/Jan/17 the El Niño-Southern Oscillation remains neutral (a La Niña event is typically associated with wetter than average conditions and an El Niño with drier conditions).

For more information: www.bom.gov.au/climate/enso/ and, <http://www.bom.gov.au/climate/iod/>

Tidal

Tidal information is relevant for the prediction of the activity of the salt marsh mosquito, *Aedes vigilax*. Typically for NSW, tides of over 1.8m can induce hatching of *Aedes vigilax* larvae and the graph below of predicted tide heights can provide some indication of when this is likely to occur.

The recent series of high tides did not reach a high level and unlikely to result in much egg hatching. The next series of high tides that may lead to *Aedes vigilax* larval hatching are over this week during 10-14/Jan/2017.

Note that actual tide heights can vary by 0.3m (or more in unusual circumstances) due to variations in atmospheric pressure, rainfall, wind and other climatic phenomena. Thus predicted tide height should be used as a gauge only for potential *Aedes vigilax* activity. The larvae of the saltmarsh mosquito relies on a inundation/drying cycle for the mudflats in which it lives; continual wet weather prevents the drying cycles thereby reducing larval production.

MVEV Climatic Models

Three predictive environmental based models for MVEV activity have been developed; the Forbes (which relies on rainfall in the river catchment basins of Eastern Australia), Nichols (based on the Southern Oscillation), and the Bennett theory (based on the Indian Ocean Dipole). The latter theory is poorly developed (and unreliable), and is not considered below. Note that all the predictive models have been developed on a limited data set and do not always forecast activity. There can also be unusual environmental conditions that may lead to the introduction of the virus to southeastern Australia, such as the movement of low pressure cells from the north to the south of the country during 2008 and 2011. Vertical transmission of the virus (from adult to the egg in *Aedes* species) can result in restricted activity following localised heavy precipitation (as per 2003 at Menindee).

i. Forbes' Hypothesis

Rainfall was not above Decile 7 in all of the river catchment basins in eastern Australia for the last quarter of 2015 or the majority of the catchments for the first quarter of 2016 (Table 1). For the Oct-Dec 2016 period, rainfall was not above Decile 7 in all of the catchment basins.

Table 1. Rainfall indices for the main catchment basins of eastern Australia as per Forbes' hypothesis, relevant to the 2016-2017 season. Note that a value of 1 equals Decile 7 rainfall.

Catchment Basin	Oct-Dec 2015	Jan-Mar 2016	Oct-Dec 2016	Jan-Mar 2017
Darling River	0.72	0.67	0.58	
Lachlan/Murrumbidgee/Murray Rivers	0.70	1.14	0.92	
Northern Rivers	1.35	0.57	0.98	
North Lake Eyre system	1.35	0.63	1.09	

ii. Nichol's Hypothesis

Table 2. The seasonal atmospheric pressures (in mm) according to Nichol's hypothesis, relevant to the 2016-2017 season.

	Autumn 2016	Winter 2016	Spring 2016
2015 Value	1010.30	1012.57	1010.07
Pre past MVEV seasons	<1009.74	<1012.99	<1009.99

Only the Winter period pertaining to the Nichol's hypothesis is in line with past MVEV active years.

*Detection via Honey-Baited Cards, the mosquito species cannot be determined.

<http://medent.usyd.edu.au/arbovirus/results/virusisolates.htm>

The Victorian Arbovirus Surveillance Program has also had a further series of Ross River virus detections at sites along the Murray, including four from Mildura and one from Kerang. These were detected during mid-December (information courtesy Stacey Rowe, DHHS, Victoria).

Total	198	4	132	38	14	3	389

[†]All of these viruses are acquired overseas, although some DENV cases may be from North Queensland. *The data in this table is updated once available from the NSW Ministry of Health.

Comment: the notifications of Ross River virus for 2016-2017 are continuing to rise and now only slightly below the long term average. During December there were 91

Ross River virus notifications being more than double the average. For January, the 32 notifications from the first week are equivalent to around half the average for the month. To date, most of the notifications are from central NSW. In contrast, Barmah Forest virus notifications have been few, being less than one tenth of the longer term average. However, the decline is probably artificial and due to the withdrawal of the commercial test that was over diagnosing patients.

It should also be noted that notifications are for NSW residents and that infection may have been acquired elsewhere.

For more data on Ross River virus notifications in NSW see:

<http://www0.health.nsw.gov.au/data/diseases/rossriver.asp>

For more data on Barmah Forest virus notifications in NSW see:

<http://www0.health.nsw.gov.au/data/diseases/barmahforest.asp>

MOSQUITO RESULTS

All the full mosquito results can be obtained from:
<http://medent.usyd.edu.au/arbovirus/results/results.htm#site>

Mosquito abundances are best described in relative terms, and in keeping with the terminology from previous NSWASP Annual Reports, mosquito numbers are depicted on the tables below as:

Each location represents the average for all trapping sites at that location.
