

# NSW ARBOVIRUS SURVEILLANCE & MOSQUITO MONITORING PROGRAM 2016-2017

## Weekly Update

Date: 10/Mar/2017

### SUMMARY

- **Climate:** over the last week, there was moderate to heavy rainfall along the ranges and coastal strip, with eastern regions of the inland having light rainfall. For February, rainfall below average for most of the state with parts of the inland very much below average. Maximum for February were up to 4-5 degrees above average.
- **Three Month Forecast:** for March to May 2017, rainfall predictions for NSW are for below average precipitation, with western areas of the state having a higher probability of being drier than average. Maximum and minimum temperatures are expected to be well above normal across the state. According to the BOM as of 28/Feb/2017, the El Niño-Southern Oscillation remains neutral, but an El Niño may form this year.
- **Tidal:** the next series of high tides that could initiate *Aedes vigilax* egg hatching are forecasted for 10-12/Mar/2017, but not predicted to be very high nor prolonged. However, current meteorological conditions have meant there has been tides 30cm higher than predicted, which has resulted in major mosquito hatches in SE Queensland, fortunately this has not occurred in the Sydney region.
- **MVEV models:** the data relevant to both the Forbes' and Nichols' hypotheses have been updated to the end of February 2017 and both theories remain inconsistent with past MVEV outbreaks.
- **Mosquito Numbers Inland:** mosquito numbers were lower this week, but 'high' (just) at Griffith and Leeton. All other locations produced 'low' numbers.
- **Mosquito Numbers Coast:** with a week of rain and cooler weather, mosquito numbers were lower this week at most sites. Ballina, Gosford and Tweed, again yielded 'high' mosquito collections.
- **Mosquito Numbers Sydney:** Both Georges River and Homebush Bay yielded 'high' numbers, but all collection were down this week with the wet, cooler weather.
- **Arboviral Isolates:** there were five arboviral isolates from Georges River this week including three Ross River and one Edge Hill virus, and one yet to be characterized flavivirus.
- **Chicken Sentinel Seroconversions:** there were no new seroconversions.
- **Human Notifications:** there were 45 Ross River virus notifications for the week 19-25/Feb.

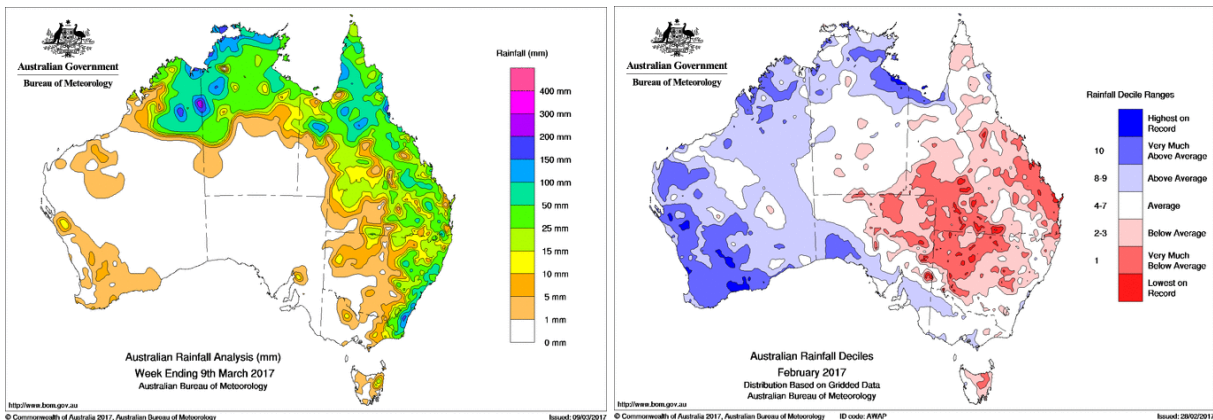

**Comment:** for the inland, the arboviral season appears over with mosquito numbers dropping notably every week and no arboviral isolates since early February. This

week for the coast, the cool wet weather meant that mosquito numbers were lower and with another wet period forecasted, collections are not expected to rise very much in the following week. The main concern was a number of arboviral isolates from Georges River. This location has historically produced a number of detections over recent years (79 detections including 9BFV, 45RRV, 11EHV and 14STRV, since 2009/2010), although relatively few human notifications.

## ENVIRONMENTAL CONDITIONS

### Rainfall

Rainfall across Australia for the week ending 9/Mar/2017 is depicted on the left and monthly rainfall deciles for February 2017 are on the right. Over the last week, there was moderate to heavy rainfall along the ranges and coastal strip, with eastern regions of the inland having light rainfall. Precipitation during February (right graph below) was below average for most of the state with parts of the inland very much below average. Maximum temperatures for February were up to 4-5 degrees above average, while minimum temperatures were around 2-3 degrees above normal. Temperatures tended to be more above average in the north of the state.

### Three Month Rainfall & Temperature Forecast

For March to May 2017, rainfall predictions for NSW are for below average precipitation, with western areas of the state having a higher probability of being drier than average. Maximum and minimum temperatures are expected to be well above normal across the state. The following pages contain graphics of the seasonal outlook:

[www.bom.gov.au/climate/outlooks/#/rainfall/median](http://www.bom.gov.au/climate/outlooks/#/rainfall/median) (Rainfall outlook).

[www.bom.gov.au/climate/outlooks/#/temperature/summary](http://www.bom.gov.au/climate/outlooks/#/temperature/summary) (Max & min temperature outlook).

According to the BOM as of 28/Feb/2017 the El Niño-Southern Oscillation remains neutral, however climatic indices suggest the possibility of an El Niño forming in 2017 (a La Niña event is typically associated with wetter than average conditions and an El Niño with drier conditions).

For more information: [www.bom.gov.au/climate/enso/](http://www.bom.gov.au/climate/enso/) and, <http://www.bom.gov.au/climate/iod/>

## Tidal

Tidal information is relevant for the prediction of the activity of the salt marsh mosquito, *Aedes vigilax*. Typically for NSW, tides of over 1.8m can induce hatching of *Aedes vigilax* larvae and the graph below of predicted tide heights can provide some indication of when this is likely to occur.

The next series of high tides that could initiate *Aedes vigilax* egg hatching are forecasted for the next few days, 10-12/Mar/2017, but are not predicted to be very high nor prolonged. However, current meteorological conditions have meant there has been tides 30cm higher than predicted, which has resulted in major mosquito hatches around southeast Queensland (M. Muller, Brisbane City Council, *pers. comm.*). Fortunately this has not occurred in the Sydney region (C. Webb, *pers. comm.*)

Note that actual tide heights can vary by 0.3m (or more in unusual circumstances) due to variations in atmospheric pressure, rainfall, wind and other climatic phenomena. Thus predicted tide height should be used as a gauge only for potential *Aedes vigilax* activity. The larvae of the saltmarsh mosquito relies on an inundation/drying cycle for the mudflats in which it lives; continual wet weather prevents the drying cycles thereby reducing larval production.

## MVEV Climatic Models

Three predictive environmental based models for MVEV activity have been developed; the Forbes (which relies on rainfall in the river catchment basins of Eastern Australia), Nichols (based on the Southern Oscillation), and the Bennett theory (based on the Indian Ocean Dipole). The latter theory is poorly developed (and unreliable), and is not considered below. Note that all the predictive models have been developed on a limited data set and do not always forecast activity. There can also be unusual environmental conditions that may lead to the introduction of the virus to southeastern Australia, such as the movement of low pressure cells from the north to the south of the country during 2008 and 2011. Vertical transmission of the virus (from adult to the egg in *Aedes* species) can result in restricted activity following localised heavy precipitation (as per 2003 at Menindee).

### i. Forbes' Hypothesis

Rainfall was not above Decile 7 in all of the river catchment basins in eastern Australia for the last quarter of 2015 or the majority of the catchments for the first quarter of 2016 (Table 1). For the Oct-Dec 2016 and Jan-Mar 2017 periods, rainfall was not above Decile 7 in all of the catchment basins.

**Table 1.** Rainfall indices for the main catchment basins of eastern Australia as per Forbes' hypothesis, relevant to the 2016-2017 season. Note that a value of 1 equals Decile 7 rainfall.

Catchment Basin	Oct-Dec 2015	Jan-Mar 2016	Oct-Dec 2016	Jan-Mar 2017*
Darling River	0.72	0.67	0.58	0.51
Lachlan/Murrumbidgee/Murray Rivers	0.70	1.14	0.92	0.92
Northern Rivers	1.35	0.57	0.98	1.10
North Lake Eyre system	1.35	0.63	1.09	0.80

\*Data for January and February 2017 only.

### ii. Nichol's Hypothesis

**Table 2.** The seasonal atmospheric pressures (in mm) according to Nichol's hypothesis, relevant to the 2016-2017 season.

	Autumn 2016	Winter 2016	Spring 2016
2015 Value	1010.30	1012.57	1010.07
Pre past MVEV seasons	<1009.74	<1012.99	<1009.99

Only the Winter period pertaining to the Nichol's hypothesis is in line with past MVEV active years.

## HUMAN NOTIFICATIONS

Weekly notifications of human mosquito-borne diseases infections are available from the NSW Ministry of Health, Communicable Disease Weekly Report and summarised in the Table below\*: [www.health.nsw.gov.au/Infectious/reports/Pages/CDWR.aspx](http://www.health.nsw.gov.au/Infectious/reports/Pages/CDWR.aspx). It should also be noted that notifications are for NSW residents and that infection may have been acquired elsewhere.

**Table 5.** Notifications of Mosquito-Borne Disease in NSW, 2016-2017\*

Week Ending	RRV	BFV	DENV <sup>†</sup>	Malaria <sup>†</sup>	CHIKV <sup>†</sup>	ZIKV <sup>†</sup>	Total

<b>Total</b>	<b>751</b>	<b>11</b>	<b>190<sup>†</sup></b>	<b>46<sup>†</sup></b>	<b>15<sup>†</sup></b>	<b>3<sup>†</sup></b>	<b>1006</b>

<sup>†</sup>All of these viruses are acquired overseas, although some DENV cases may be from North Queensland. \*The data in this table is updated once available from the NSW Ministry of Health.

*Comment:* high notifications of Ross River virus disease for 2016-2017 are continuing with another 45 cases reported, although cases from the inland are on the decline and the outbreak has long ended. The December 2016 and January 2017 notifications are the highest since 2013 (Table 6). The total for this period was 617 notifications and this is several times higher than for the most recent years during the comparable period; e.g. 2015-2016 (96), 2014-2015 (207), and 2013-2014 (63). In comparison to previous years that had high case numbers in December and January, the season of 2005-2006 had 295 notifications, and 1998-1999 produced 276. The difference for this season highlights the dramatic nature of the outbreak.

The activity in Victoria has been even more dramatic, with more than 1,600 confirmed cases of Ross River virus for just this year.

Barmah Forest virus disease notifications continue to be very low despite a series of arboviral detections. This decline appears to be artificial and due to the withdrawal of the commercial test that was over diagnosing patients.

**Table 6.** Ross River virus infection notifications in NSW residents, by month of disease onset per fiscal year. Jul 2013 to February 2017\*.

## MOSQUITO RESULTS

All the full mosquito results can be obtained from:  
<http://medent.usyd.edu.au/arbovirus/results/results.htm#site>

Mosquito abundances are best described in relative terms, and in keeping with the terminology from previous NSWASP Annual Reports, mosquito numbers are depicted on the tables below as:

Each location represents the average for all trapping sites at that location.

### Inland

Location	Mosquito	Oct-16					Nov					Dec					Jan-17					Feb				Mar
